trave a function denoted as

f(x1, x2, ..., x2) N-Dimensional

then, define partial derivative as follows

$$\frac{\partial f}{\partial x_i} = \lim_{\delta x \to 0} \frac{f(x_1, \dots, x_i + \delta x_i, \dots, x_n) - f(x_1, \dots, x_i, \dots, x_n)}{\delta x_i}$$

f(x,,xz,...,5xi,...xn)-f(x,xz,...,xn)

Now, define a gradient

 $\nabla f = \begin{pmatrix} \frac{\partial f}{\partial x_1} \\ \frac{\partial f}{\partial x_2} \\ \dots \\ \frac{\partial f}{\partial x_n} \end{pmatrix}$ 

\* (x12x5)

Note, Gradient at the illustrated point provides a better view of the function Behavior.

In Egn(b), we have

$$f(x_1, x_2) \simeq f(a, b) + \frac{\partial f}{\partial x_1}(x_1 - a) + \frac{\partial f}{\partial x_2}(x_2 - b)$$
 (6)

Motivation: Use the gradient function to measure the behavior of the Loss function, And to update the Weights ( \tak | \hi=1,..., N \hat{\chi} ) in such a way to reduce minimize the loss function along its fastest descent direction. (Steepest)

The Technique to achieve this is Based on Taylor Expansion Series

Consider f(x), we can write it in

a Standardized way.
